ABSTRACT: A three-component annulation reaction was developed for the synthesis of pyrroles, a class of compounds with various properties valuable to biomedical and polymer industries. Treatment of α -silylaryl triflates, Schiff bases, and alkynes generated polysubstituted pyrroles in good yields (61–86%) with regioselectivity. This domino reaction involved completion of five sequential steps in a single flask, which comprised aryne formation through 1,2-elimination, their alkylation by Schiff bases through 1,2-addition, 1,4-intramolecular proton transfer, Hüisgen 1,3-dipolar cycloaddition, and dehydrogenative aromatization. It was then successfully applied as the key step in the synthesis of the natural product lamellarin R. This new reaction represents an efficient, sustainable process for the production of chemical materials.

INTRODUCTION

Pyrrole is a five-membered heterocyclic aromatic compound, which darkens readily upon exposure to air. Although pyrrole is not naturally occurring, many of its derivatives are found in natural products.¹ Examples include chlorophylls, porphyrins, vitamin B_{12} , and so forth. Pyrrole-containing secondary metabolites include lamellarin, prodigiosin, rhazinilam, ryano-dine, sceptrin, and so forth. It is of interest to note that pyrrole is also a constituent of tobacco smoke.²

As a flat and electron-rich ring, pyrrole is susceptible to electrophilic attack and can react with numerous biomolecules. Thus, it becomes an important constituent of well-established drugs, such as atorvastatin, chlorfenapyr, premazepam, pyrvinium, roseophilin, tolmetin, and zomepirac.³ The pyrrole scaffold is used to construct therapeutic agents with antibacterial, anticancer, antifungal, anti-inflammatory, anti-malarial, antimicrobial, antiprotozoal, antipsychotic, antiviral, antitubercular, and anxiolytic properties among others.^{4,5} This molecule also plays an active role as a component of polymers and indigoid dyes.⁵ In catalytic reactions, pyrroles are widely used for corrosion inhibition, metallurgy, polymerization, and preservation.⁵

Many methods have been developed for the synthesis of pyrroles,^{6–11} such as the aza-Wittig reaction, the Hantzsch reaction, the Paal–Knorr condensation reaction, carbenoid insertions, the Friedel–Crafts acylation, the Heck coupling, hydroarylations, and the Michael addition. Quiclet-Sire and Zard¹² provided elegant convergent routes to pyrroles by exploiting unusual radical chemistry.

Schiff bases have been used in pyrrole synthesis. Examples include Ag-catalyzed tandem 1,3-dipolar cycloaddition/aroma-

tization by Hu and Wang,¹³ Cu-catalyzed three-component cyclization by Kostakis and Lykakis,¹⁴ the Cu-catalyzed cascade process involving (3 + 2) cycloaddition of azomethine ylide by Lu and Wang,¹⁵ Li-mediated annulation,¹⁶ and phosphonite-mediated 1,3-dipolar cycloaddition by Cyr and Arndtsen.¹⁷ Many other established methods for pyrrole generation require the use of expensive or toxic metal catalysts, some of which produce harmful waste streams.^{18–20} These concerns inspired us to develop a novel and efficient approach for the synthesis of pyrroles with various substituents through a domino reaction.

Implementation of our newly developed method as the key step in the synthesis of natural products (e.g., lamellarins) would affirm its efficiency and applicability. Lamellarins are pyrrole-derived marine alkaloids with diverse biological properties.²¹ This versatility makes lamellarins important subjects for research. They are often used as a starting point for the design of anticancer and antiviral compounds.²² In addition, efforts have been devoted to the invention of new and improved methods for lamellarin synthesis.^{23,24}

Herein, we report on a newly developed method for the direct synthesis of polysubstituted pyrroles from α -silylaryl triflates 1, Schiff bases 2, and alkynes 3. It involves a "single-flask" reaction. It possesses advantages of a few synthetic steps,

a moderate reaction temperature, and metal-free conditions and provides good regioselectivity and yields. This domino reaction was applied as the key step in the synthesis of lamellarin R, a tetrasubstituted natural pyrrole.

RESULTS AND DISCUSSION

The feasibility of the new method for the synthesis of the polysubstituted pyrroles shown in Scheme 1 was investigated.

Scheme 1. "Single-Flask" Synthesis of Pyrroles 4 from α -Silylaryl Triflates 1, Schiff Bases 2, and Alkynes 3

A mixture of (trimethylsilyl)aryl triflates 1 (1.0 equiv), Schiff bases 2 (1.0 equiv), and alkynes 3 (1.2 equiv) was treated with fluoride (2.0 equiv) in acetonitrile at 25 °C. During the optimization of the new reaction conditions, different combinations of solvents, fluorides, additive of 18-crown-6, temperatures, and reaction times were studied for the synthesis of pyrrole 4acb. The data in Table 1 reveal that the reaction could be conducted in THF (entries 1–5), acetonitrile (entries

6–8), and toluene (entries 9 and 10). Acetonitrile was the best solvent (entry 8). Among the three fluorides n-Bu₄NF, CsF, and KF, the use of CsF without 18-crown-6 produced the highest yields of pyrroles (86% in entry 8). This annulation process proceeded well at 25 °C; elevation of the reaction temperature was unnecessary.

After 2.0 h of stirring under a nitrogen atmosphere followed by 6.0 h of stirring in open air, pyrroles **4aab–dbb** were often isolated in 61–86% yields with purity >99.2%. Regarding green chemistry characteristics, the atom economy²⁵ was calculated to be 62.8%, whereas the atom efficiency²⁶ was 54.0% for compound **4acb**.

Various starting materials were used to evaluate the scope of this new reaction. The methoxy group was allowed to attach to the benzene nucleus of α -silylaryl triflates 1. The benzene nucleus could be replaced by a pyridine ring (i.e., 1d). Methyl, methoxy, chloro, and bromo groups could be attached to the phenyl terminal (R^3) in Schiff bases 2. This phenyl group could also be replaced by a naphthyl, furyl, and thienyl group (i.e., 2f, 2g, and 2h, respectively). The alkyl terminal group of the Schiff bases 2 must have a methylene unit that was attached to an electron-withdrawing alkoxycarbonyl group. The two substituents in alkynes 3 could be hydrogen atoms, alkyl, acetyl, alkoxycarbonyl, or methoxyphenyl groups. The use of these starting materials often led to the desired pyrroles in 61-86% yields (Table 2). The exception involved the use of inactivated alkyne 3g, which had alkyl groups on both sides of the carbon to carbon triple bond. As a result, product 4acg was obtained only up to 15% yield.

To appraise the new reaction processes, we applied the new annulation reaction as the key step in the synthesis of lamellarin R (9, Scheme 2). Cesium fluoride (3.0 equiv) in

acetonitrile was added to a solution containing (methoxy)silylphenyl triflate **1b** (1.2 equiv), Schiff base **2i** (1.0 equiv), and bis(methoxyphenyl)acetylene (**3h**, 1.2 equiv). Reagents **1b** and **3h** are commercially available; Schiff base **2i** is readily available through the simple condensation of glycine methyl ester hydrochloride with paraformaldehyde.²⁷ After the annulation reaction proceeded at 0–10 °C for 6.0 h, the desired pyrroles *para*-**4bih** and it's regioisomer *meta*-**4bih** were generated in a ratio of 2.3:1. Finally, the isolated pyrrole *para*-**4bih** (61%) underwent demethylation with BBr₃ in methanol at room temperature to produce lamellarin R (**9**) in a high yield by use of Jia's method.²³

For verification of its configuration conclusively, the molecular framework of compound **4acb** was obtained through single-crystal X-ray diffraction analysis. The data and ORTEP

Our design and concerns in the development of a single-flask method for the synthesis of pyrroles 4 from triflates, Schiff bases, and alkynes are described in Scheme 1. The α -silylaryl triflates 1 first react with cesium fluoride to generate aryne intermediates 5 through 1,2-elimination (step 1).²⁸ Then, Schiff bases 2 are added to arynes 5 in situ to produce iminium carbanions 6 through 1,2-addition (step 2). The carbanion center in betaines 6 may trap an acidic proton nearby to generate azomethine ylides 7 through 1,4-intramolecular proton transfer (step 3).²⁸ Subsequently, the Hüisgen 1,3dipolar cycloaddition takes place between ylides 7 and alkynes 3 to give the (3 + 2) cycloadducts 8 (step 4). Noteworthily, the activated acetylenes 3 as the starting material are expected to be more competitive than the solvent acetonitrile for reacting with azomethine ylides 7. Autoxidation in open air^{29,30} would then lead the 3-pyrrolines 8 to pyrroles 4 as the final products (step 5). In a control experiment, a compound with a similar framework to intermediates 8 but with a CH₂ unit between the CO_2R^3 group and the pyrroline ring was produced. It was found inert to the dehydrogenative aromatization.

Results from our trials indicate that the dehydrogenative aromatization of pyrrolines 8 indeed proceeded gradually at 25 °C.³¹ The smooth conversion of $8 \rightarrow 4$ was facilitated by the presence of a CO_2R^3 group attached directly to the C2 position of 3-pyrrolines 8. Activity of the allylic hydrogen at the α position to the CO_2R^3 group increases significantly. Thus, pyrrolines 8 with such a framework are well-suited for dehydrogenative aromatization.

This approach to pyrrole synthesis accomplishes five steps sequentially in a single flask. This new domino reaction offers the following benefits: 1. The reaction generates the desired products in good-to-high yields at room temperature without any involvement of harsh conditions or reagents. 2. The entire "single-flask" reaction can be conducted with ease without isolation of the intermediates.

Application of this new reaction as the key step in the synthesis of the natural product lamellarin R (9) allowed the establishment of one pyrrole nucleus, three anisole moieties, and one ester functionality in its scaffold in a single flask. In the reaction shown in Scheme 2, a byproduct *meta*-4bih was isolated in a 26% yield. Its generation was due to two possible 1,2-additions of Schiff bases 2i to an unsymmetrical benzyne intermediate. Thus, the addition may occur at both the meta and the para positions.

CONCLUSIONS

Polysubstituted pyrroles can be synthesized from silylaryl triflates, Schiff bases, and alkynes through an aryne-induced domino reaction. The overall pathway comprises 1,2-elimination, 1,2-nucleophilic addition, 1,4-proton transfer, (3 + 2) cycloaddition, and dehydrogenative aromatization. This reaction was applied successfully as the key step in the synthesis of lamellarin R.

Utilization of this new method in chemical synthesis minimizes waste production and reduces the need for extra reagents, solvents, and labor. Hence, this three-component synthetic protocol is ecologically and environmentally benign for the production of fine chemicals.
